Description

This invention relates to therapeutically beneficial strains of bacteria, and particularly to strains of *Lactobacillus acidophilus*.

L. acidophilus is a component of the normal intestinal flora of most healthy human beings. The genus *Lactobacillus* is widely distributed in nature. Many species, such as *L. bulgaricus* and *L. casei*, are found in dairy products, as well as in fruits and vegetables. Other *Lactobacillus* species are encountered in the intestinal tract of mammals and insects. For many centuries, lactobacilli have been used in milk and dairy products as fermentation organisms, producing yogurt and various types of fermented and soured milks, curds and creams. The species of *Lactobacillus* used in the dairy industry is generally *L. bulgaricus*, although *L. acidophilus* strains have been used fairly extensively as well.

In recent years a number of studies have been carried out using *L. acidophilus* strains isolated at North Carolina State University ("NCSU"). These studies have yielded evidence that the NCSU strains, when ingested by humans or animals, produce beneficial effects on various functions of the gastrointestinal tract, including the suppression of activation of chemical carcinogens in the large bowel, a reduction of fecal excretion of cholesterol (related to a reduced risk of large bowel cancer), and a reduction of gastrointestinal side effects of antibiotic therapy.

The present invention features a new strain which exhibit a number of characteristics which render them beneficial to human health, and in particular render them useful in the treatment of the side effects of antibiotic therapy, ulcerative colitis, and constipation; in providing resistance to gastrointestinal colonization by pathogenic microorganisms and yeasts; in reducing fecal cholesterol excretion; and in reducing fecal estrogen excretion.

The strains of the invention are characterized in that an average of at least 50, more preferably at least 100, of the bacteria can adhere to one human small intestinal mucosal cell after a five minute incubation of the bacteria with the cells. Preferably, the bacteria are further characterized in that they produce at least 3.5 milliequivalents ("meq") of lactic acid per 10^{10} CFU (colony forming units) in nutrient medium at 37°C per day; they are capable of proliferating at 37°C in nutrient medium at a pH value of 3.0; they are capable of proliferating in nutrient medium containing 0.1% oxgall bile; and they exhibit a generation time of less than one hour in nutrient medium at 37°C. ("Nutrient medium" refers to any culture medium containing the nutrients required for the proliferation of *L. acidophilus* bacteria.)

The invention also provides a method for isolating strains of the invention from a sample containing a multiplicity of bacterial strains, involving carrying out, in any order, the screening steps of isolating bacteria of the species *L. acidophilus*, and associating the bacteria with gastrointestinal cells and selecting bacteria capable of adhering to the cells at a rate of an average of at least 50, and more preferably at least 100, bacterial cells per gastrointestinal cell in a five-minute incubation period. The selection method also includes the steps of incubating bacteria of the sample in nutrient medium at a pH value of 3.0 and selecting bacteria which proliferate in that medium; incubating bacteria in nutrient medium at 37°C and selecting bacteria that produce at least 3.5 milliequivalents of lactic acid per 10^{10} CFU per day; incubating bacteria of the sample in nutrient medium containing at least 0.1% bile and selecting bacteria which proliferate in that medium; and incubating bacteria of the sample with nutrient medium and selecting bacteria having a generation time of less than one hour at about 37°C.

Other features and advantages of the invention will be apparent from the following description of preferred embodiments thereof, and from the claims.

Description of the Preferred Embodiments Strain Isolation

Healthy human beings carry bacteria of the species *L. acidophilus* as part of their normal flora, generally in concentrations of about 10 lactobacilli per gram of intestinal contents; thus a healthy individual harbors in excess of 10 lactobacilli in his intestinal tract. The first step in the method is to screen faecal specimens from humans and select those in which high lactobacillus concentrations are present.

Next, these samples are screened using a procedure designed to isolate strains exhibiting the characteristics discussed in the Summary of the Invention, above, and which can briefly be summarized as:

- (1) Stability to acid
- (2) Stability to bile (a property previously identified as desirable by the Department of Food Science, North Carolina State University)
- (3) Ability to attach avidly to mucosal cells of the human intestinal tract
- (4) Lactic acid production
- (5) Hardy *in vitro* growth.

Stability to Acid and Bile

Screening for stability to bile, and for stability to a somewhat acidic environment, is accomplished as follows. LBS agar (described in J. Bacteriol. (1951) 62, 132) is prepared, having the following composition, per liter:

Triptycose and Peptone	10.0g
Yeast Extract	5.0g
Ammonium Citrate	2.0g
Monopotassium Phosphate	6.0g
Dextrose	20.0g
Polysorbate PO ₄	1.0g
Sodium Acetate Hydrate	25.0g
Magnesium Sulfate	0.575g
Manganese Sulfate	0.12g
Ferrous Sulfate	0.034g
Agar	15.0g

To 84 grams of powder of the above composition, dehydrated, are added 300 ml of tomato juice and 800 ml distilled water and, following mixing, 1.32 ml acetic acid. 1.5 g oxgall bile is then added, and the pH adjusted to 5.5 using 1M HCl. Plates are stored in an anaerobic chamber 1-3 days prior to use and then used without autoclaving. Fecal specimens from healthy individuals are homogenized in water, under anaerobic conditions, and serial dilutions incubated on the plates for 48 hours in an anaerobic chamber. The bacteria which proliferate on the plates are selected and screened further. This step eliminates many of the microorganisms in the sample.

Screening for stability to more acidic conditions is carried out using MRS broth (Difco; described in J. Applied Bacteriol. (1960) 23, 130), of the composition:

Bacto-Protease Peptone #3	10.0g
Bacto-Beef Extract	10.0g
Bacto-Yeast Extract	5.0g
Dextrose	20.0g
Tween 80	1.0g
Ammonium citrate	2.0g
Sodium acetate	5.0g
Magnesium sulfate	0.1g
Manganese sulfate	0.05g
Disodium phosphate	2.0g

55g of powder of the above composition, dehydrated, is mixed with 1000 ml distilled water and sterilized by autoclaving for 15 min. at 15 lb. The broth has a final pH value of 6.5 at 25 °C. The pH is then adjusted using 1.0 M HCl and, if necessary, 1.0 N NaOH, and the broth filter sterilized. Bacteria are incubated in the broth for 48 hours in an anaerobic chamber. Selected bacteria preferably can proliferate at pH below 3.5, preferably at pH 3.0.

L. acidophilus Selection

The next screening step is the isolation, from the bacteria able to proliferate in acid and bile, of bacteria of the species *L. acidophilus*. This step is carried out using standard microbiological techniques. Adherence

The next step is to test acid and bile-stable bacteria for the ability to adhere to gastrointestinal cells. Human gastrointestinal cells are first isolated, by any convenient method. One technique involves the collection of the effluent from a patient with a well-functioning ileostomy by saline lavage.

The saline effluent is collected in cold 1/10 volume buffer I (0.1% gelatin, 1% glucose, 500 mM sodium phosphate, pH 7.4). This solution is then filtered through #25 silk to remove clumps and debris and the small intestinal (ileal) mucosal cells collected by centrifugation at 100 x g for 10 min. The cells are then washed in buffer II (0.45% NaCl, 0.1% glucose, 0.01% gelatin, 50 mM sodium phosphate, pH 7.4) using the

same centrifuge conditions. Finally, the cells are resuspended in buffer II, 1/3 volume of tissue culture medium NCTC 135 is added, and the cells are stored at 4°C until use. Ileal cell number and viability are determined by Trypan Blue staining. The human ileal cells can be frozen in liquid nitrogen after the addition of 10% (v/v) glycerol.

5 The bacteria are grown for 18 hours at 37°C in MRS broth with 8 μ Ci of 3 H-alanine and 3 H-leucine added. The bacteria are then washed in 5 volumes of phosphate buffered saline, resuspended in buffer II, and filtered through 2.0 μ polycarbonate filters to remove clumps. The bacteria are then mixed with the human small intestinal cells, incubated at 37°C, and samples taken 5 minutes later. The samples are placed on 2.0 μ polycarbonate filters and the excess liquid removed by gentle suction. The filters are then
10 rinsed, first with 2 ml then with 5 ml of phosphate buffered saline (pH 7.4). Using these filters the ileal cells and attached bacteria are retained but the free bacteria pass through. Controls include the reaction mixture without the human small intestinal cells. The radioactivity retained is determined by liquid scintillation. The bacterial specific activity is determined from the colony forming units calculated from the optical density at 550 nm and the radioactivity retained by 0.2 μ filters. The bacterial specific activity is used to calculate the
15 numbers of bacteria bound.

Bacteria which bind, according to the above procedure, at a rate of at least 50, and more preferably 100, bacteria per gastrointestinal cell (representing approximately 10% of the bacteria contacted with the cells) are the desired bacteria.

20 Lactic Acid Production

Lactic acid production is measured by incubating bacteria in MRS broth or Scott Peptone Yeast Broth under anaerobic conditions and measuring lactic acid at 8 or 24 hours using gas-liquid chromatography. Selected bacteria produce at least 3.5 meq, and more preferably over 4 meq, of lactic acid per 10^{10} CFU at
25 37°C in a 24-hour period.

Hardy Growth

The final screening step is the selection of bacteria which exhibit hardy growth *in vitro*, as measured by
30 generation time. 5×10^6 CFU of bacteria are used to inoculate nutrient medium, e.g., MRS broth, and CFU measured at 1, 2, 3, 4, 5, 6, 7, and 8 hours by plating 0.1 ml of diluted aliquots onto LBS agar and incubating plates for 48 hours at 37°C under anaerobic conditions. Bacteria are selected which have a generation time, at 37°C, of less than one hour, more preferably about 45 minutes.

35 Screening Rationale

Each step in the above screening procedure is designed to isolate strains possessing characteristics which render them capable of enhancing human health.

40 Acid and bile stability are important because the bacteria are ingested and must pass through the acidic environment of the stomach as well as the bile-containing small intestine, and they must be able to survive and proliferate under these conditions if the bacteria are to confer health benefits on the person ingesting them.

Adherence is important because this property permits the bacteria to colonize and become established in the gastrointestinal tract.

45 Lactic acid production is important because it is believed that the lactic acid produced by the bacteria is in part responsible for the beneficial effects of colonization of the gastrointestinal tract by the strains of the invention. Lactic acid is an antimicrobial substance, and its production by the strains of the invention can help them form a protective barrier to pathogens within the gastrointestinal tract. Lactic acid may also aid in the inactivation of carcinogens in the gastrointestinal tract.

50 Hardy *in vitro* growth is an important property because the strains of the invention must be produced on a large scale; hardy growth is also an indicator that the bacteria will likely grow well *in vivo* as well.

Characteristics of Strain GG

55 One strain of the invention, designated GG, has the following characteristics.

Acid Stability

The GG strain can grow at pH 3.0 up to a concentration of 1×10^7 CFU. At higher pH's the growth is even higher, achieving 10^9 CFU at pH 5.0.

In normal human gastric juice, the GG strain, starting at an inoculum of 10^8 CFU, can survive, with less than 2 log decline in inoculum size, for at least 30 minutes at pH 2.5.

Bacteria of the GG strain (10^9 CFU) were inoculated down a Levine tube directly into the stomach of a healthy volunteer. With gastric contents at pH 1.0-2.0, at least 1,000 organisms of the GG strain survived for a minimum of two hours.

Bile stability

The GG strain could grow in oxgall bile at a concentration of 0.15% in LBS agar.

Adherence to Intestinal Mucosal Cells

The table below shows the extent of adherence of bacteria of the GG strain to ileal mucosal cells.

TIME OF EXPOSURE	NO. OF BACTERIA BOUND PER INTESTINAL CELL
5 minutes	119
10 minutes	235
15 minutes	333

Lactic Acid Production

The production of lactic acid was measured by gas liquid chromatography, following incubation of the GG strain in liquid nutrient broth. The following lactic acid concentrations were measured, at the given times of incubation.

TIME OF INCUBATION	LACTIC ACID PRODUCTION
8 hours	1.53 meq/ 10^8 CFU
24 hours	4.44 meq/ 10^{10} CFU

Generation Time

The GG strain exhibited hardy growth *in vitro*. Using an initial inoculum of 5×10^4 CFU in MRS broth, the strain showed a 40-fold increase in growth during a four-hour period, reaching a density of 2×10^6 CFU. Thus, during this four-hour period there were 5.2 generations, giving a single generation time of 45 minutes.

Use

The strains of the invention can be cultured on a large scale and used therapeutically, in lyophilized form or in conjunction with a pharmaceutically acceptable carrier substance, and can be added to food products, particularly dairy products such as milk and yogurt, as has been done with *L. acidophilus* strains for many years. The bacteria of the strains, alone, in food, or in other carrier vehicles, can be taken orally by a human patient, in an effective amount (e.g., 10^6 - 10^{10} bacteria per person per day) to treat or prevent a variety of medical disorders, mentioned above and now discussed in more detail. Culture conditions are as follows.

A stock solution consists of sterile skim milk containing 10^{10} CFU viable organisms. 1 ml of this stock solution is added to 2 liters of MRS broth. The vessel is placed in an anaerobic incubation chamber and grown overnight for 14 hours with general stirring at 37°C . The broth is centrifuged at $10,000 \times g$ for 20

minutes, and the pellet is resuspended in 50-100 ml of sterile skim milk and stored at -80°C .

In one particular mode of administration, 10^9 to 10^{10} organisms are added to milk, either in volumes of 10 to 20 ml, or larger volumes, e.g., 250 to 500 ml. The milk is administered once daily, so that 10^9 to 10^{10} CFU are given in a single administration. For animals, 0.2 to 1.0 ml of the stock milk solution is mixed into their food, so that they receive 10^9 to 10^{10} CFU of the bacteria daily.

Side Effects of Antibiotic Therapy

Diarrhea is the major complication of antibiotic treatment, occurring in approximately 10% of patients receiving antibiotics, particularly ampicillin, amoxacillin, cephalosporins, clindamycin, erythromycin, and tetracyclines. The strains of the invention can be used to treat antibiotic-induced diarrhea, in the same manner that *L. acidophilus* preparations have been used in the past. In addition, the strains can be used, prior to or concurrently with antibiotic therapy, as a prophylaxis. Such prophylactic administration should occur within 24 hours of the antibiotic therapy.

Ulcerative Colitis

Idiopathic ulcerative colitis, also known as inflammatory bowel disease, represents a difficult therapeutic problem. The disease is rather common, and patients suffer recurrent attacks of diarrhea, which can appear on multiple occasions over years of active disease. At the present time the only therapies that have proven successful are salicylazosulfapyridine (SAS) and corticosteroids. Many patients relapse despite these treatments. In addition, the treatments themselves are associated with a high incidence of side effects.

Several lines of evidence have suggested that the intestinal microflora is involved in this disease process, either as an initiator or as a determinant of symptoms.

Bacteria of the strains of the invention can be administered, as described above for antibiotic side effects, to treat or prevent ulcerative colitis.

Constipation

Sluggish bowel action and chronic constipation are major problems in older people. Constipation leads to abdominal distention, cramps, and general malaise. The interest of the general public in promoting good bowel activity is reflected in the panoply of products available in the drugstore for alleviating this condition. These products vary from harsh laxatives, to short chain fatty acids, to various natural fiber products, such as pectins, lignins, gums, and mucilages.

Cultured dairy products, yogurts, and soured milks have been employed throughout history to aid chronic constipation.

Bacteria of the strains of the invention can be employed alone, as described above, or can be admixed with a sub-therapeutic dose of lactulose, a synthetic disaccharide which has been used to treat constipation. The lactulose will be metabolized by the bacteria, enhancing their beneficial effect without producing the side effects which are sometimes associated with therapeutic doses of lactulose.

Colonization Resistance

It has become apparent in recent years that colonization of the gastrointestinal tract in humans provides a reservoir for dissemination of pathogenic microorganisms, especially in immunocompromised hosts. The intestinal microflora of healthy individuals can resist implantation of undesirable microorganisms through a number of internal control mechanisms. While these control mechanisms are poorly understood, the net result is relative stability of the human intestinal flora, with maintenance of the same types and same concentrations of bacteria over long periods of time.

Through the impact of antibiotic treatment, undesirable microorganisms are able to colonize the gastrointestinal tract. Among the bacteria, these undesirable organisms include *Pseudomonas*, *Enterobacter*, *Serratia*, *Klebsiella*, *Citrobacter* and *Proteus-Providencia*. Fungi can also colonize the gut, especially yeasts such as *Candida*.

While healthy individuals can withstand intestinal colonization even during antibiotic treatment, immunocompromised hosts face a serious threat in this circumstance. These undesirable microorganisms can invade the mucosa, producing septicemia and life-threatening illness.

The clinical settings in which intestinal colonization with undesirable microorganisms become important include cancer, especially in those patients treated with potent chemotherapy; inherited or acquired

immunodeficiency syndromes; patients treated with corticosteroids for a variety of conditions; and recipients of organ transplants such as kidney, bone marrow, heart, and liver. There are also elderly, debilitated patients who are colonized and eventually infected by these undesirable microorganisms. Among infants, admission to intensive care units often is associated with antibiotic treatment, poor nutritional status, and immunocompromising conditions. This group of high-risk children is also challenged by the problems of colonization with potentially pathogenic bacteria and yeasts.

Maintenance of the natural resistance to overgrowth by undesirable microorganisms is known in the recent scientific literature by the term "colonization resistance" (CR). Various ploys have been undertaken to either enhance colonization resistance or, alternatively, prevent overgrowth by intestinal microorganisms. Enhancement of CR is achieved by using antibiotics that produce only minimal effects in the composition of the normal intestinal flora, especially by maintaining the normal anaerobic components that seem to be responsible for resisting overgrowth by undesirable microorganisms. The alternative method is prevention of colonization by administering oral antibiotics that essentially kill off any new entrants into the microflora. This method produces a "sterile" microflora, at least for short periods of time.

While each of these methods to prevent colonization has certain attractions, they are not necessarily effective. Relatively few therapeutic antibiotics are able to maintain the CR, so this ploy is often unsuccessful. The other method involving administration of oral antibiotics produces many side effects of its own, and it is often unsuccessful since highly resistant microorganisms may colonize even in the presence of antimicrobial drugs. Thus, the problems of colonization by undesirable microorganisms in immunocompromised hosts, whether adults or children, remains a major problem in modern medicine.

Bacteria of the strains of the invention can be administered to patients, as described above, to provide CR in a benign way, since the bacteria have no intrinsic pathogenicity. Colonization of the intestine by this natural organism could prevent other pathogenic forms from entering the flora, while at the same time maintaining a relatively healthy intestinal environment.

Cholesterol Excretion

Considerable interest has been aroused in recent years in the fecal excretion of sterols, particularly cholesterol, since there may be a correlation with colon cancer. Studies in experimental animals, carried out over a decade ago, showed that chemically-induced colon cancer could be augmented by increased excretion of cholesterol in the feces.

It has been known for some time that cholesterol undergoes an enterohepatic circulation, resulting in intestinal reabsorption of some cholesterol and fecal excretion of the remainder. Within the large intestine cholesterol is subjected to microbial reduction to coprostanol and coprostanone. Most individuals excrete the majority of cholesterol as these reduced end products, but approximately 20% of people excrete mostly pure cholesterol, with only small amounts of the reduction products.

While these animal studies were interesting, their relevance was not held to be significant, until clinical trials on cholesterol-lowering drugs were published. These studies showed that the cholesterol-lowering drugs, such as atomid, were successful in reducing serum cholesterol levels and in reducing heart attacks. The corollary, however, was an increase in large bowel cancer, for the lowering of serum cholesterol came at the expense of increasing fecal cholesterol. These clinical trials verified the results seen in animals, whereby higher levels of fecal cholesterol were associated with increased risk of colon cancer.

Bacteria of the strains of the invention can be administered to patients, as described above, to reduce the amount of cholesterol excreted in the patients' feces.

Estrogen Excretion

Improvements in laboratory techniques for measuring estrogens have widened our understanding of these important sex hormones. Estrogens are produced largely in the ovaries and, to a lesser extent, in fat and other tissues. The major excretion of estrogens are via the urine.

An important development in recent years is understanding the enterohepatic circulation of estrogens. It has been shown that as much as half of circulating estrogens are recycled throughout the bile into the intestinal tract, where they are reabsorbed into the body. Only 5% of estrogens are excreted in the feces.

In order to be excreted in the bile, estrogens are conjugated, generally as a glucuronide or sulfonate. These conjugated estrogens pass through the bile into the intestinal tract, where they are deconjugated by intestinal bacteria and subsequently reabsorbed.

The importance of the enterohepatic circulation was shown in studies by Adlercreutz et al., in which fecal and urinary estrogens were tested in women receiving ampicillin for a minor infection. This oral

antibiotic caused a 30% reduction in excretion of urinary estrogens, with a concomitant increase in fecal estrogen excretion. The explanation is that the antibiotic suppressed bacteria within the intestine responsible for deconjugating the estrogens. This led to decreased intestinal reabsorption, and increased fecal excretion of estrogens.

Many studies have established that higher estrogen levels in urine and plasma are correlated with increased risk of breast cancer. This appears to fit with the observation that vegetarian women, having lower levels of urine and plasma estrogens, have reduced rates of breast cancer.

Bacteria of the strains of the invention can be administered, as described above, to menstruating women to lower the amount of excreted estrogen; the same deconjugating enzymes involved in estrogen reabsorption are influenced by ingestion of *L. acidophilus*.

Deposits

The GG strain was deposited in the American Type Culture Collection, 12301 Parklawn Drive, Rockville, Maryland 02852, United States of America, on 15 April 1985 and has been given ATCC Accession No. 53103.

Claims

1. A biologically pure culture of a strain of bacteria deposited in the ATCC under Accession No 53103, said bacteria being characterized in that an average of at least 50 of said bacteria can adhere to one human small intestinal mucosal cell after a five minute incubation of said bacteria with said cell, in that said bacteria produce at least 3.5 milliequivalents of lactic acid per 10^{10} Colony Forming Units (CFU) in nutrient medium at 37°C in a 24-hour period, in that said bacteria are capable of proliferating in nutrient medium at a pH value of 3.0, in that said bacteria are capable of proliferating in nutrient medium containing at least 0.1% bile and in that said bacteria exhibit a generation time of less than an hour in nutrient medium at 37°C .
2. A culture according to claim 1 in which said bacteria have a generation time of 45 minutes at 37°C .
3. A culture according to claim 1 or 2 in which said bacteria are capable of proliferating in at least 0.15% oxgall bile in LBS agar.
4. A culture according to claim 1, 2 or 3, further characterized in that an average of at least 100 of said bacteria can adhere to one human small intestinal cell after a five minute incubation of said bacteria with said cells.
5. A method of isolating a therapeutically useful strain of bacteria deposited in the ATCC under Accession No 53103 said method comprising carrying out the following screening steps, in any order, on a sample containing a multiplicity of bacterial strains:
 - a) Isolating from said sample bacteria of the species *Lactobacillus acidophilus*, and
 - b) coincubating bacteria of said sample with gastrointestinal cells and selecting bacteria which
 - (1) are capable of adhering to said cells at a rate of an average of at least 50 bacteria cells per gastrointestinal cell in five minutes of coincubation,
 - (2) proliferate in nutrient medium at a pH value of 3.0,
 - (3) proliferate in nutrient medium containing at least 0.1% bile,
 - (4) produce at least 3.5 milliequivalents of lactic acid per 10^{10} colony forming units in nutrient medium at 37°C in a 24 hour period, and
 - (5) exhibit a generation time of less than an hour in nutrient medium at 37°C .
6. A composition comprising a strain of bacteria as claimed in any one of claims 1 to 4 together with a pharmaceutically acceptable carrier substance.
7. A composition as claimed in claim 6 wherein the pharmaceutically acceptable carrier substance is a dairy product food.
8. A composition comprising a strain of bacteria as claimed in any one of claims 1 to 4 in a lyophilized form.

9. A strain of bacteria as claimed in any one of claims 1 to 4 for administration to humans or animals to have a beneficial therapeutic or prophylactic effect in the gastro-intestinal tract.
10. A strain of bacteria as claimed in claim 9 for use in humans in combatting gastro-intestinal side effects of antibiotic therapy.
11. A strain of bacteria as claimed in claim 9 for use in humans in the treatment of ulcerative colitis.
12. A strain of bacteria as claimed in claim 9 for use in the treatment of constipation.

Patentansprüche

1. Biologisch reine Kultur eines bei der ATCC unter der Nummer 53103 hinterlegten Bakterienstammes, dadurch gekennzeichnet, daß im Mittel wenigstens 50 der Bakterien an einer einzigen menschlichen Dünndarm-Schleimhautzelle anhaften können, nachdem eine fünfminütige Inkubation der Bakterien mit den Zellen stattgefunden hat, daß die Bakterien in einer Zeitspanne von 24 Stunden wenigstens 3,5 Milliäquivalente Milchsäure je 10^{10} Kolonie bildende Einheiten (CFU) in Nährmedium bei 37°C erzeugen, daß die Bakterien in der Lage sind, in Nährmedium bei einem pH-Wert von 3,0 zu proliferieren, daß die Bakterien in der Lage sind, in wenigstens 0,1% Galle enthaltenden Nährmedium zu proliferieren, und daß die Bakterien eine Generationszeit (Reproduktionszeit) von weniger als einer halben Stunde im Nährmedium bei 37°C zeigen.
2. Kultur nach Anspruch 1, in der die Bakterien eine Reproduktionszeit von 45 Minuten bei 37°C haben.
3. Kultur nach Anspruch 1 oder 2, bei der die Bakterien in der Lage sind, in wenigstens 0,15% Galle von Ochsegallen in LBS Agar zu proliferieren.
4. Kultur nach einem der Ansprüche 1, 2 oder 3, dadurch gekennzeichnet, daß im Mittel wenigstens 100 der Bakterien an einer einzigen menschlichen Dünndarmzelle nach einer fünfminütigen Inkubation der Bakterien mit diesen Zellen anhaften.
5. Verfahren zum Isolieren eines therapeutisch verwendbaren, bei der ATCC unter der Nummer 53103 hinterlegten Bakterienstamms, bei dem die nachfolgenden Screening-Schritte in beliebiger Reihenfolge an einer Substanzprobe ausgeführt werden, die eine Vielfalt von Bakterienstämmen enthält:
 - a) Isolieren von Bakterien der Spezies *Lactobacillus* aus der Substanzprobe und
 - b) Koinkubieren der Bakterien aus der Substanzprobe mit gastrointestinalen Zellen und Selektieren von Zellen, die
 - (1) in der Lage sind, an den Zellen mit einer mittleren Rate von wenigstens 50 Bakterienzellen je Gastrointestinal-Zelle innerhalb von 5 Minuten Koinkubation anzuhaften,
 - (2) in Nährmedium bei einem pH-Wert von 3,0 zu proliferieren,
 - (3) in Nährmedium, das wenigstens 0,1% Galle enthält zu proliferieren,
 - (4) innerhalb einer Zeitspanne von 24 Stunden wenigstens 3,5 Milliäquivalente Milchsäure je 10^{10} Kolonie bildende Einheiten in Nährmedium bei 37°C produzieren und
 - (5) eine Generationszeit von weniger als 1 Stunde in Nährmedium bei 37°C zeigen.
6. Zusammensetzung, die einen Bakterienstamm gemäß einem der Ansprüche 1 bis 5 sowie eine pharmazeutisch verträgliche Trägersubstanz aufweist.
7. Zusammensetzung nach Anspruch 6, bei der die pharmazeutisch verwendbare Trägersubstanz ein als Nahrungsmittel vorgesehenes Molkereiprodukt ist.
8. Präparat, das einen Bakterienstamm gemäß einem der Ansprüche 1 bis 4 in lyophilisierter Form enthält.
9. Bakterienstamm nach einem der Ansprüche 1 bis 4 zur Verabreichung an Menschen und Tiere zum Erzielen eines günstigen therapeutischen oder prophylaktischen Effektes in dem Gastro-Intestinal-Trakt.

10. Bakterienstamm nach Anspruch 9 zur Verwendung bei Menschen bei der Bekämpfung von gastro-intestinalen Nebenwirkungen einer Antibiotika-Therapie.

11. Bakterienstamm nach Anspruch 9 zur Verwendung bei Menschen bei der Behandlung von Colitis ulcerosa.

12. Bakterienstamm nach Anspruch 9 zur Verwendung bei der Behandlung von Verstopfung.

Revendications

1. Culture biologiquement pure d'une souche bactérienne déposée à l'ATCC sous le numéro de dépôt 53103 ladite souche de bactéries étant caractérisée en ce qu'un nombre d'au moins 50 bactéries appartenant à ladite souche peuvent adhérer à une petite cellule de la muqueuse intestinale humaine au bout de cinq minutes d'incubation de ladite souche bactérienne avec ladite cellule, en ce que ladite souche de bactéries produit au moins 3,5 milliéquivalents d'acide lactique par 10^{10} UFC (Unités Formant des Colonies) en 24 heures dans un milieu nutritif à 37°C en ce que ladite souche bactérienne est capable de proliférer dans un milieu nutritif à pH 3,0, en ce que la dite bactérie est capable de proliférer dans un milieu nutritif contenant au moins 0,1% de bile et en ce que le temps de génération de ladite bactérie est de moins d'une heure dans un milieu nutritif à 37°C .

2. Culture selon la revendication 1 dans laquelle ladite bactérie a un temps de génération de 45 minutes à 37°C .

3. Culture selon la revendication 1 ou 2 dans laquelle ladite bactérie est capable de proliférer dans du milieu agar LBS contenant au moins 0,15% de bile de boeuf.

4. Culture selon la revendication 1, 2 ou 3 caractérisée de surcroît en ce qu'un nombre d'au moins 100 bactéries appartenant à ladite souche peuvent adhérer à une petite cellule de la muqueuse intestinale humaine au bout de cinq minutes d'incubation de ladite souche bactérienne avec lesdites cellules.

5. Méthode d'isolement d'une souche bactérienne déposée à l'ATCC sous le numéro de dépôt 53103 utile d'un point de vue thérapeutique, ladite méthode comprenant les étapes de sélection suivantes, dans un ordre quelconque, à partir d'un échantillon contenant plusieurs souches bactériennes:

a) l'isolement de l'espèce Lactobacillus acidophilus à partir dudit échantillon de bactéries,

b) la co-incubation de bactéries dudit échantillon avec des cellules gastro-intestinales et la sélection de bactéries qui:

(1) sont capables d'adhérer auxdites cellules à un taux de 50 cellules bactériennes, en moyenne, par cellule gastro-intestinale en cinq minutes de co-incubation,

(2) prolifèrent dans un milieu nutritif à un pH de 3,0,

(3) prolifèrent dans un milieu nutritif contenant au moins 0,1% de bile,

(4) produisent au moins 3,5 milliéquivalents d'acide lactique par 10^{10} UFC (Unités Formant des Colonies) dans un milieu nutritif à 37°C en 24 heures et

(5) présentent un temps de génération de moins d'une heure dans un milieu nutritif à 37°C .

6. Composition contenant une souche bactérienne selon les revendications 1 à 4 ainsi qu'une substance pharmaceutiquement acceptable utilisée comme support.

7. Composition selon la revendication 6 dans laquelle la substance pharmaceutiquement acceptable utilisée comme support est un produit laitier.

8. Composition contenant une souche bactérienne selon l'une des revendications 1 à 4 sous forme lyophilisée

9. Souche bactérienne selon l'une des revendications de 1 à 4 destinée à être administrée à l'homme ou à des animaux dans un but thérapeutique ou prophylactique au niveau du système gastro intestinal.

10. Souche bactérienne selon la revendication 9 destinée à être administrée à l'homme afin de combattre les effets secondaires de l'antibio-thérapie au niveau du système gastro-intestinal

EP 0 199 535 B2

11. Souche bactérienne selon la revendication 9 destinée à être administrée à l'homme dans le traitement de la rectocolite hémorragique.

5 12. Souche bactérienne selon la revendication 9 destinée à être administrée à l'homme dans le traitement de la constipation.
